CHAPTER 1 INTRODUCTION

1.1 Background

There have been a few published demand forecasts of infrastructures in Asia. Among them, Infrastructure for a Seamless Asia (2009) published by ADB and ADB Institute is the most frequently referred study up to now. This study estimated the infrastructure demand (from year 2010 to 2020) in Asia is estimated would be around 8 trillion USD. Asian Development Bank (hereinafter referred to as “ADB”) reviewed the study and published another report titled “Meeting Asia’s Infrastructure Needs”, in February 2017. In this report, the demand for four economic sectors (power, communication, transportation, and water sanitation sectors) from 2016 to 2030 is estimated. This report also estimated that the developing countries/areas in Asia need to invest a total amount of 26.2 trillion USD (in 2015 prices) from 2016 to 2030, 1.7 trillion USD annually (including costs for climate change measures) to keep up the current economic growth. Without costs for climate change, 22.6 trillion USD in total and 1.5 trillion USD annually are required. JICA and ADB have had a discussion on the studies and they agreed to conduct a joint research to review the above demand forecast of infrastructures until 2030 in Asia.

Other than the four economic sectors that ADB has already estimated for, there are many other social sectors such as education, health and disaster prevention sectors. In order to estimate accurately the total amount that Asian countries need to invest, it is desirable to forecast the demands for these social sectors too.

Based on the above discussions, JICA has launched the research project titled “The Research on the Infrastructure Demand Forecast in Asia,” for macro level estimation and micro level data collection targeting the social and disaster prevention sector as well as urban railways.

1.2 Objectives of the Study

The objective of the study is to collect basic information and data on mass rapid transit (MRT) analyze them and forecast the future needs of MRT as a part of “The Research on the Infrastructure Demand Forecast in Asia.”

1.3 Flow of the Study

The study forecasts the total MRT length needed by 2030 and the investments in MRT development expected between 2016 and 2030.

1.4 Target Countries

Table 1-1 below shows the countries targeted by this study which are twenty four in total. It has to be noted that this study does not include China.

Table 1-1 List of Target Countries

| Area | Country | No. |
|---------------------|---|------------|
| West & Central Asia | Afghanistan, Armenia, Azerbaijan, Georgia, Kazakhstan, Kyrgyzstan, Pakistan, Tajikistan, Turkmenistan, Uzbekistan | 10 |
| East Asia | Mongolia | 1 |
| South Asia | Bangladesh, Bhutan, India, Nepal, Sri Lanka | 5 |
| Southeast Asia | Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippine, Thailand, Vietnam | 8 |
| Total | | 24 |

CHAPTER 2 ASSESSMENT OF MRT NEEDS

2.1 Introduction

Figure 2-1 summarizes the flow of the study for determining the MRT needs and estimating the cost. The first section reviews the literatures on MRT development, and it is followed by analysis on identifying the MRT operation timing. Then the socioeconomic data of the target countries are analyzed and cities with the prospect of MRT development are identified. The last two sections estimate the MRT length and cost needed, respectively.

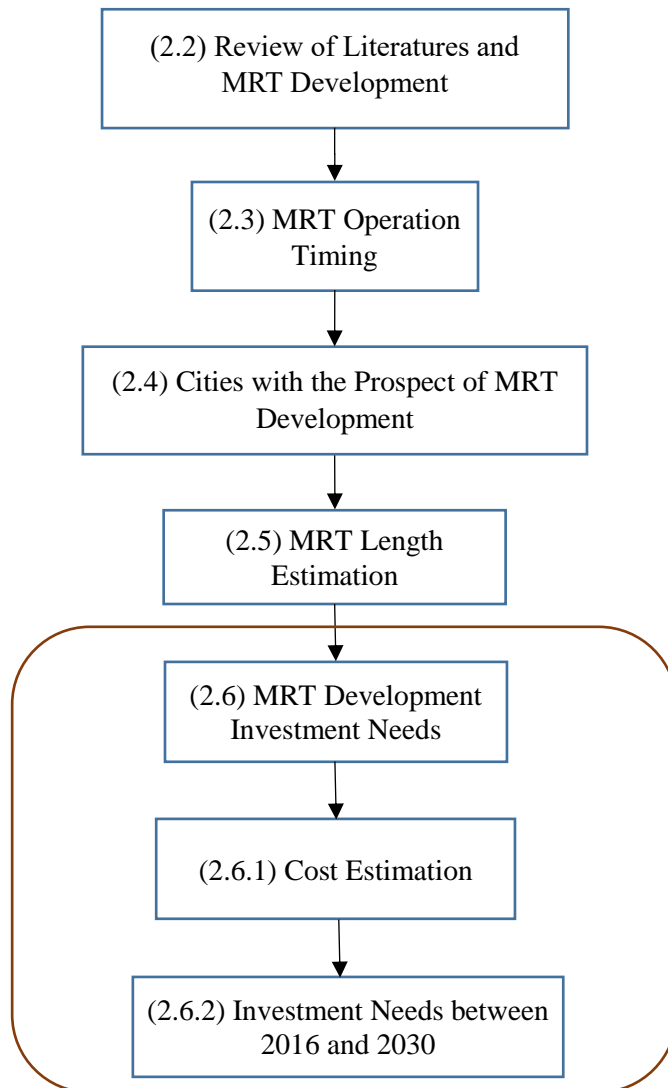

Figure 2-1 Study Flow for Estimating MRT Infrastructure Needs

2.2 Review of Literatures and MRT Development

Different studies have been conducted to estimate the infrastructure demand. Fay and Yapes (2003) estimated infrastructure demand based on socioeconomic variables. They estimated the global demand based on data across countries and for different sectors including road and rail sectors. Bhattacharyay (2010) used similar approach, but to estimate infrastructure demand in Asia and the Pacific between 2010 and 2020.

Asian Development Bank (ADB) and Asian Development Bank Institute (ADBI) jointly projected

infrastructure needs for developing Asia in 2009, and the projection was updated in 2017 by the ADB. In 2009, ADB and ADBI estimated the infrastructure needs from 2010 to 2020 of 32 developing member countries in its report titled “Infrastructure for a Seamless Asia”. The study which covered four infrastructure sectors, including the transport sector, projected that the investment needs would be slightly above 8.22 trillion USD (in 2008 prices). In 2017, the ADB updated the above investment needs in its report titled “Meeting Asia’s Infrastructure Needs”. Unlike the 2009 study, this one covered all 45 developing countries, and the fifteen years between 2016 and 2030, and it estimated that developing Asia would need to invest 26 trillion USD (in 2008 prices).

Unlike the above studies which covers various sectors, the Japan International Cooperation Agency (JICA) conducted studies focusing on the transport sector. In 2011, JICA published a report on a research on urban transport planning titled “The Research on Practical Approach for Urban Transport Planning”. This research, which is very much related to this study, reviews the existing urban transport system developments. It relates the urban transport system developments with the urban socio-economic conditions for the formulation of medium- and long-term development strategies according to urban socio-economic development. The study mainly divides the urban transport into two: mass rapid transit (MRT) and bus rapid transit (BRT) system. Light rail transit (LRT) and monorails are covered under the MRT, and the study assesses the prospect of MRT as well as BRT system development and timing.

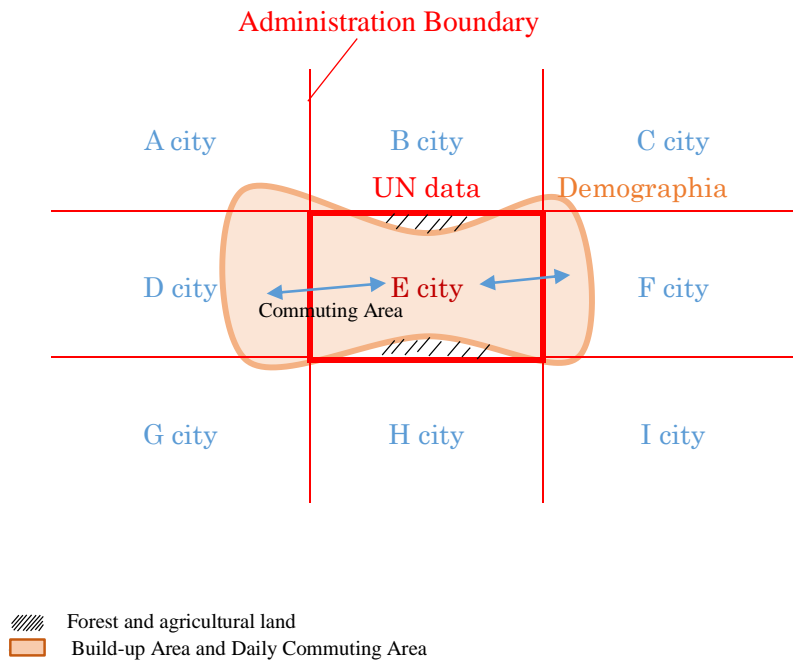

This study fundamentally updates the above JICA study, but only limited to the MRT part. Unlike the 2011 JICA study, the MRT here does not cover monorails or LRT as they have different transport characteristics and their unit costs may significantly vary. Moreover, this study revises the future MRT needs and establish more reliable relationships between the urban socio-economic changes and the length of the MRT needed.

2.3 MRT Operation Timing

The JICA (2011) study identified the city GDP level at which a city is likely to operate by analyzing historical socioeconomic status of the cities with MRT. The study found that most of the cities started their first MRT operation when their GDP was between 3 billion USD and 30 billion USD (in 2000 prices). It should be noted that the city GDP here is estimated as the product of the national GDP per capita published by the World Bank and the urban population the United Nation (World Urbanization Prospect).

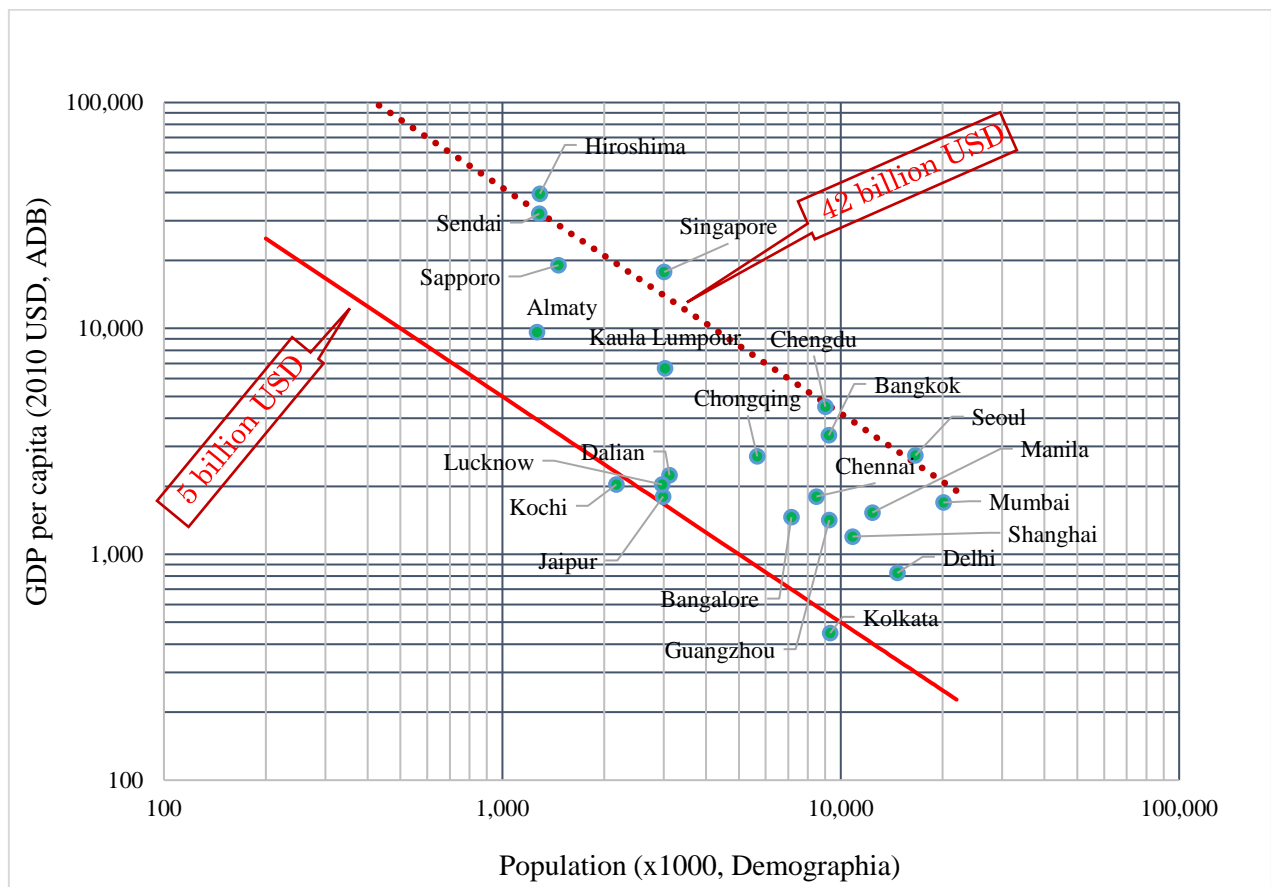

The MRT operation timing is analyzed based on similar data, but updated based on the GDP of 2010 prices. Moreover, the urban population from *Demographia* is used in combination with the urban growth rates provided by the UN for more consistency with the urban area data provided by *Demographia* used in this study. *Demographia* refers to a continuously built-up land mass within a labor market as an urban area. Therefore, it provides more consistent areas for mega cities like Bangkok, Jakarta or Delhi where different area figures are reported. While the areas of the UN data coincide with the administrative boundaries, those of *Demographia* can include the areas of the adjacent cities. The difference of the definitions on urban area between *Demographia* and the UN data is illustrated in Figure 2-2.

Figure 2-3 below shows the updated graph of the MRT operation timing. The 3 billion USD lower bound (in 2000 prices) increased to 5 billion USD (in 2010 prices), and the upper bound increased from 30 billion USD (in 2000 prices) to 42 billion USD (in 2010 prices). Although the location of some of the cities has relatively changed, the result shows a pattern similar to that of the updated JICA (2011) study which is based on the UN data. As a result, any city with GDP of 5 billion USD or more (i.e., the product of urban population and national GDP per capita in 2010 prices) may be considered to have the potential to operate MRT.

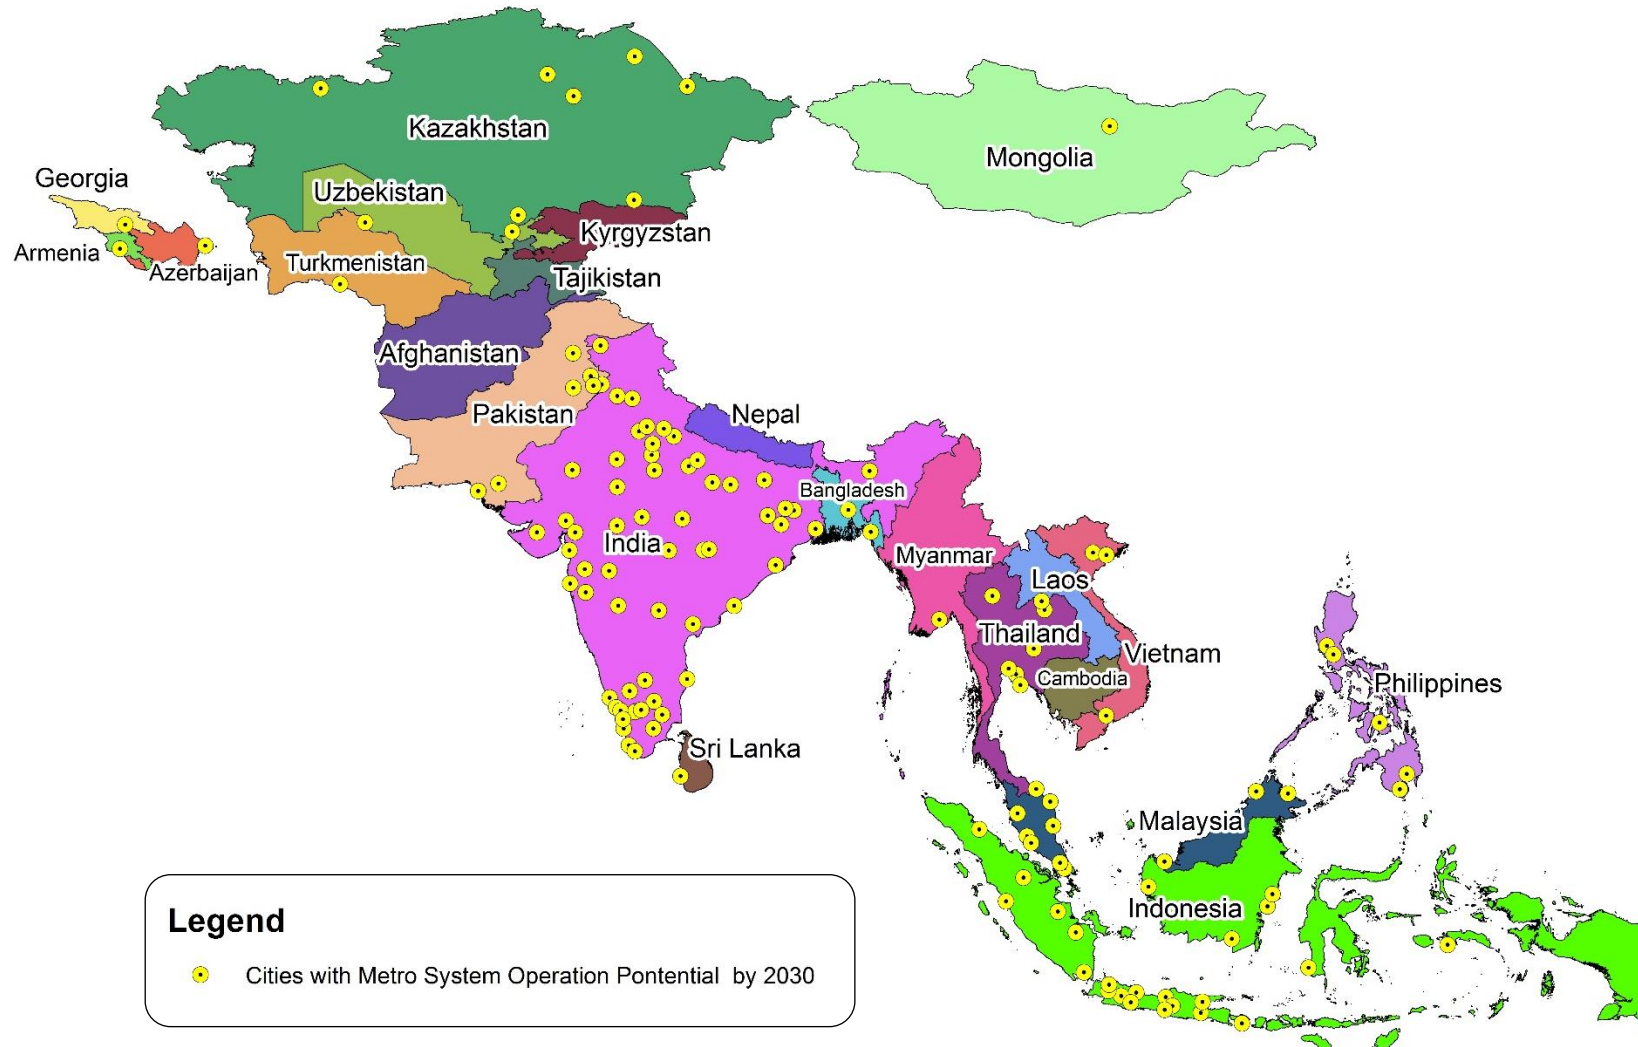

Figure 2-3 GDP per Capita and Urban Population at First MRT Operation

2.4 Cities with the Prospect of MRT Development

Considering the time needed for appraisal and development, cities which need MRT by 2030 are targeted in this study. Section 2.3 has identified that any city with GDP of 5 billion USD (in 2010 prices) or above has the potential to develop MRT. Therefore all cities with GDP of 5 billion USD or more (i.e., the product of urban population and national GDP per capita in 2010 prices) are considered to have the potential to operate MRT.

Based on the above requirement (i.e., 5 billion USD city GDP threshold), all the cities with the potential to operate MRT by 2030 are identified (refer to Appendix 2 for the list of the cities). The cities are further classified into those, which as of now, operating MRTs, those with MRT development plans, and those without plans. The classification is based on the readily available information, and reconfirmation is advised on the latest plans and status of each candidate city.

Figure 2-4 shows all the cities of the target countries with the potential of operating MRT by 2030 (i.e., those with at least 5 billion USD GDP). It includes cities with less than one million population but satisfying the GDP criteria.

2.5 MRT Length Estimation

2.5.1 MRT Length Estimation Model

This study used a regression model to establish the relationship between the MRT length and socioeconomic status of the cities, based on the MRT development and socioeconomic data collected. The MRT development data include existing and planned MRT length of cities from candidate countries. The planned MRT development is included under the assumption that the development will be realized as planned.

The MRT length and MRT density (MRT length per 1,000 inhabitants) are considered as the dependent variables of the regression model, and their correlations with different explanatory variables (including GDP, urban population, urban density and urban area) were analyzed (refer to Appendix 3).

Figure2-6 shows a typical correlation pattern observed by the study. As the figure confirms regression models with different combinations and numbers of explanatory variables are possible, and study analyzed and compared different such regression models. Different analyses were also conducted by grouping different countries (such India, other countries) and compared the regression model results.

Source: JICA Study Team

Figure 2-6 Correlation Coefficients

Several regression models were compared using length and MRT density as dependent variables, and combinations of the remaining variables as independent variables. As the case shown in Table 2-1 demonstrates, independent variables, except the urban area, could not explain the total length significantly. In addition, it is difficult to obtain future urban area data, which makes difficult to use this model to the forecast the future MRT length. In contrast, the t-values of the GDP per capita and urban area are significant for the MRT density model, and as such the study decided to forecast the future MRT needed based on the MRT density.

Table 2-1 MRT Length Estimation Models Options

| Variables | Total length as a dependent variable | | MRT density as a dependent variable | |
|---|--------------------------------------|---------|-------------------------------------|---------|
| | Coefficients | t-value | Coefficients | t-value |
| GDP per capita (USD /person) | 0.000275 | 0.06 | 0.000902 | 4.13 |
| Urban area (km ²) | 0.055454 | 4.48 | 0.001319 | 2.16 |
| Urban density (people/km ²) | 0.001687 | 0.17 | 0.000234 | 0.48 |
| Adjusted R ² | 0.63 | | 0.74 | |

As explained above, future MRT length needs are estimated based on a model using MRT density as a dependent variable. MRT density models with three variables (GDP per capita, urban area and urban density) as independent variables and two variables (GDP per capita, urban area) were compared (Table 2-1). As a result, it was found that adding the third variable (urban density) does not improve the model. Therefore, the following MRT model with two variables was estimated and used to forecast MRT length:

$$\text{Length}/1,000 \text{ inhabitants} = \beta_1 * \text{GDP per capita} + \beta_2 * \text{Urban area}$$

Where *Length* is MRT length in meter, *GDP per capita* in 2010 USD prices, and *Urban area* in kilometer square of urban agglomeration. Table 2-2 below shows the summary of the estimation result of the model with two and three explanatory variables.

Table 2-2 MRT Length Estimation Model Results

| Variables | <i>Two variables</i> | | <i>Three variables</i> | |
|------------------------------|----------------------|-----------------|------------------------|-----------------|
| | Coefficients | <i>t</i> -value | Coefficients | <i>t</i> -value |
| GDP per capita (USD /person) | 0.000912 | 4.24 | 0.000902 | 4.13 |
| Urban area (km2) | 0.001392 | 2.37 | 0.001319 | 2.16 |
| Urban density (people/km2) | Not applicable | | 0.000234 | 0.48 |
| Adjusted R2 | 0.75 | | 0.74 | |

It should be noted that the sample cities of the above regression model include cities like Jakarta which planned mostly light rail transit (rather than MRT). As a result, the exclusion of Jakarta alone significantly improve the above model, which may be more appropriate for MRT oriented cities. But the cities like this still have the potential to develop MRT and reorient their current transport system development policies.

2.5.2 Estimates of Future MRT Length

The MRT length needed by a city at different socioeconomic level is estimated based on the regression model explained in Section 2.5.1 above. The lengths needed are estimated for each city at first, then tallied all for the overall MRT length need in the target cities by 2030. Input values for variables and estimation results are listed in Appendix 2 and 5 respectively. According to the result, the cities in the target countries that meet the socioeconomic requirement need 3,199 km MRT length by 2030.

2.6 MRT Development Investment Needs

2.6.1 Cost Estimation

Preliminary analysis of the cost data obtained show significant variation not only across countries but even within a country. Therefore, the samples used in the cost estimation are not country-wise but project-wise. The average cost of the MRT is affected by various factors, including the proportion that runs underground (Figure 2-7). Generally the MRT cost per km increases with the increase of the GDP per capita of a country, but the data analyses showed more complex situation as indicated in Table 2-3, in which you can see the cost per km is higher in countries like Bangladesh and Viet Nam than Malaysia. Countries like Bangladesh and Viet Nam which are introducing MRT for the first time outsource the work, and local involvement is limited. That could be one of reason behind the relatively higher cost of MRT in lower GDP countries introducing the MRT for the first time. But this trend is expected to change as the future when the capacity of the local firms develops (like India's current situation) and the firms start to undertake significant portion of the work.

India shows the lowest MRT cost on average (52 million USD/km), although significant variation of costs is observed even for the same underground proportion (Figure 2-7). But the average cost of the yen-loan projects in India is higher than the total average and it is about 76 million USD/km. The involvement of local companies in the MRT development may be the main reason behind the relatively lower average cost than other countries, but the sources of the differences between yen-loan and non-yen-loan projects are not

clear at this point.

The study considered different options of accounting the variation of the costs explained above. For example the cost is estimated separately for India and the rest of the target countries, and other options considered includes dividing the target countries by region (as dry and wet region countries). However, the representativeness of the results have become the main concern, as the samples are not only limited by unevenly distributed. The division of the samples into India and the rest of the countries, has understandably led to statically better results for Indian samples but poorer for samples from the rest of the countries.

Figure 2-7 MRT Cost by Underground Proportion

Table 2-3 Distribution and Characteristics the MRT Projects

| Country | Number of samples | Total length (km) | Elevated (km) | Under-ground (km) | Under-ground (%) | Cost (million USD/km) |
|-------------|-------------------|-------------------|---------------|-------------------|------------------|-----------------------|
| Bangladesh | 1 | 20.1 | 20.1 | 0 | 0.0% | 137 |
| Indonesia | 1 | 15.7 | 9.2 | 6.5 | 41.4% | 82 |
| India | 26 | 1070.7 | 774.2 | 296.5 | 27.7% | 52 |
| Mongolia | 2 | 28.7 | 13.2 | 15.5 | 54.0% | 68 |
| Malaysia | 2 | 103.2 | 80.2 | 23.0 | 22.3% | 129 |
| Pakistan | 1 | 27.1 | 25.4 | 1.7 | 6.3% | 59 |
| Philippines | 2 | 35 | 24 | 11 | 30.4% | 77 |
| Thailand | 8 | 209.8 | 161.2 | 48.6 | 23.2% | 76 |
| Viet Nam | 11 | 141.8 | 74.0 | 67.8 | 47.8% | 140 |
| All | 54 | 1652 | 1181 | 470 | 28.5% | 70 |

As explained above, different cost estimation options have been considered to account for the cost variation, but each option comes with its own merits and demerits. Although the variation of the cost across countries or regions is important, the objective of this study is to estimate the total cost in the target countries as a whole, and not by country or region. Therefore, the study estimated the average cost by using all samples of the target countries and establishing the relationship between the total cost and elevated length, underground length, and GDP per capita based on the projects in the study area. In addition, the study compared cost models with additional explanatory variables to the underground length and elevated length variables (which are quite related to the cost) and found the following model to explain the prevailing relationship best among the compared models:

$$\text{Total cost} = \beta_1 * \text{Elevated length} + \beta_2 * \text{Underground length} + \beta_3 * \text{GDP per capita}$$

Where *Total cost* is in million USD in 2016 prices, *Elevated length* in km, *Underground length* in km, and *GDP per capita* of 2016 in 2010 USD prices. Table 2-44 shows the estimation result of the cost model with two and three explanatory variables.

Table 2-4 MRT Cost Estimation Model Results

| Variables | Two variables | | Three variables | |
|------------------------------|-----------------------|---------|-----------------|---------|
| | Coefficients | t-value | Coefficients | t-value |
| Elevated length (km) | 43.90 | 7.35 | 26.40 | 5.59 |
| Underground (km) | 94.68 | 7.25 | 75.69 | 8.09 |
| GDP per capita (USD /person) | <i>Not applicable</i> | | 0.29 | 7.62 |
| Adjusted R2 | 0.79 | | 0.89 | |

2.6.2 Investment Needs between 2016 and 2030

Total MRT length needed between 2016 and 2030 is estimated to be 3,199 km, as explained in Section 2.5.2. But only 789 km was built by the end of 2015. Therefore, the MRT length needed between 2016 and 2030 is 2,410 km (i.e., subtracting 789 km from 3,199). The investments needed are estimated using cost estimation model in Section 2.6.1. The percentage of underground length is assumed to be 28.5%, which is the average of all the sample projects from target countries shown in Table 2-53, in all target cities. The estimation results for each city are listed in Appendix 5.

The total investment needed by 2030 and investment made by 2015 are estimated at 275 billion USD and 48 billion USD in 2016 prices, respectively (using cost estimation model in Section 2.6.1). The estimate of the investment made by 2015 is based on the cost estimation model, and not on the actual investment data. As a result, the investment in MRT needed between 2016 and 2030 is 227 billion USD in 2016 prices (i.e., by subtracting investment made by 2015 from that needed by 2030). The summary of the estimation result is shown in Table 2-55. The investment needed in MRT between 2016 and 2030 is about 5 times of that made until 2015, and indicates how important it is for the economic growth of Asia.

Table 2-5 The Estimation Result of Investment Needs

| | by 2015 | 2016–2030 | Total |
|---------------------------|----------------|-----------------|-----------------|
| Estimated Length (km) | 789 | 2,410 | 3,199 |
| Estimated Investment Cost | 48 billion USD | 227 billion USD | 275 billion USD |

Trial Calculation of Gap between Need and Actual Investment

Although the total investment need between 2016 and 2030 is estimated to reach 227 billion USD, the actual investment is not expected to meet the need. The model itself is estimated based on only cities operating or planning to operate MRT, and the length estimated by applying this model does not reflect the actual MRT development of all similar cities. In another words, there are cities with socioeconomic level similar to that of the cities operating or planned to operate MRT, but have not developed MRT.

To estimate the proportion of the MRT that would be actually realized, the study estimated the MRT need in terms of length in 2015 and compared it with the actual development just for reference. The result of this analysis shows that the total MRT length built by 2015 was only 58.01% of the need. Assuming that this trend would continue in the future, it is estimated that actual investment in MRT development would reach 159 billion USD in 2016 prices by 2030 (i.e., 58.01% of the investment needed). And the actual investment in MRT between 2016 and 2030 would be 111 billion USD, which is estimated by subtracting 48 billion USD from 159 billion USD. This amount is only 48 % of the original needs (i.e.,227 billion USD). To fill the gap between the needs and the actual investment, the governments should build investment plans earlier and also secure sufficient funds for investments.

Note:

- *Demographia* (2017) population data are used and extended 2030 using by growth rates by the UN data
- GDP is from ADB and in 2010 prices
- City GDP here is estimated as the products of the city population and GDP per capita

Appendix 3
